Abstract

With the rapid increase in energy consumption across industries and retail sectors, efficient power management has become a critical concern. Traditional methods of monitoring and forecasting energy usage are often manual, inaccurate, and inefficient, leading to wastage and higher costs. This project proposes a Predictive Modeling System that leverages Machine Learning (ML) techniques to forecast and optimize energy demand on a store-wise basis.

The system gathers historical data including store energy consumption, customer footfall, time of day, weather conditions, and appliance usage. Using this data, ML algorithms such as Random Forest, ARIMA, and LSTM are applied to predict future energy demands. The predictive model is integrated with an optimization module, which helps in reducing unnecessary energy consumption, managing peak loads efficiently, and lowering operational costs.

By implementing this AI-driven system, businesses can achieve real-time monitoring, smart energy planning, and automated decision-making, promoting cost efficiency, sustainability, and intelligent energy management. The solution is scalable and adaptable, suitable for retail chains, industrial complexes, and smart city infrastructures.

Keywords: Predictive modeling, Energy forecasting, Store-based ML, Optimization, Power management, LSTM, ARIMA, Smart energy system.

Chapter 1

Introduction

Energy management has always been a major concern for commercial establishments, retail chains, and industrial sectors. Each store or facility has different energy consumption patterns, influenced by factors such as customer footfall, operational hours, weather conditions, and types of appliances used. Inefficient energy usage not only increases operational costs but also contributes to environmental issues such as higher carbon emissions.

Traditional energy management techniques are largely manual or rule-based, which fail to adapt to dynamic energy demands and often result in wastage of electricity during low-demand periods or shortages during peak hours. To overcome these limitations, predictive modeling using machine learning has emerged as an effective solution.

The Store-Based Machine Learning Model predicts energy demand for individual stores by analyzing historical data. This data-driven approach allows for accurate forecasting and real-time optimization of energy usage. Machine learning algorithms such as Random Forest, ARIMA, and LSTM are applied to identify patterns in energy consumption, while optimization techniques help reduce unnecessary energy costs and improve operational efficiency.

Implementing a predictive modeling system for efficient power management provides several benefits:

1. Accurate Demand Forecasting: Predict future energy needs based on historical patterns.
2. Cost Reduction: Optimize energy usage to lower electricity bills.
3. Resource Efficiency: Reduce wastage and allocate energy where it is needed most.
4. Sustainability: Contribute to eco-friendly energy practices.
5. Scalability: Can be implemented across multiple stores, industries, and smart cities.

In summary, this project combines artificial intelligence, machine learning, and optimization algorithms to create a smart energy management system that is both efficient and sustainable, addressing the challenges of modern power consumption.

1.1 Motivation

Energy consumption is rapidly increasing in retail, commercial, and industrial sectors, creating challenges for efficient power management. High electricity costs, energy wastage, and fluctuating demand make traditional energy management techniques insufficient. Many businesses still rely on manual monitoring or static scheduling, which is inefficient, time-consuming, and prone to errors. The motivation behind this project comes from the need to create a smart, automated, and predictive system that can:

1. Forecast energy demand accurately for each store or facility.
2. Optimize energy usage, reducing unnecessary consumption and costs.
3. Adapt to dynamic patterns, such as seasonal variations, peak hours, and changing customer behavior.
4. Promote sustainability by minimizing energy wastage and reducing carbon footprint.
5. Provide real-time insights and decision-making tools for energy managers.

By combining machine learning algorithms (like Random Forest, ARIMA, LSTM) with optimization techniques, this system addresses real-world challenges in energy management. The ultimate motivation is to help businesses save money, reduce energy waste, and contribute to a sustainable future, while paving the way for intelligent energy solutions in smart cities and modern industries.

1.2 Problem Definition

With the increase in energy consumption across retail and industrial sectors, managing power efficiently has become a significant challenge. Each store or facility has unique energy usage patterns influenced by customer footfall, time of day, weather conditions, and appliance types. Traditional energy management approaches are manual, static, and unable to predict future demand, leading to:

- Excess energy consumption during low-demand periods
- Higher electricity costs
- Difficulty in real-time monitoring and control
- Inability to make data-driven decisions for optimization

The problem definition of this project is:

"To develop a predictive modeling system using machine learning that can accurately forecast store-wise energy demand and optimize power usage in real-time, thereby reducing energy wastage, lowering costs, and promoting sustainable energy management."

This system will use historical energy consumption data, customer footfall, weather data, and operational parameters to train machine learning models like Random Forest, ARIMA, and LSTM. The output predictions will guide energy optimization algorithms to ensure efficient power management for each store or facility.

1.2.1 Challenges with Existing Methods

Traditional energy management techniques face several challenges in modern retail and industrial environments:

1. Manual Monitoring:
   - Energy usage is often tracked manually or using static schedules.
   - Leads to human errors and delays in decision-making.
2. Inefficient Forecasting:
   - Existing systems cannot accurately predict future energy demand for individual stores.
   - Overestimation or underestimation leads to wastage or shortages.
3. Lack of Real-Time Optimization:
   - Traditional methods cannot dynamically adjust energy consumption based on real-time conditions.
4. Uniform Energy Management:
   - One-size-fits-all energy policies are applied across multiple stores or facilities.
   - Fails to account for store-specific patterns and variations.
5. High Operational Costs:
   - Inefficient energy usage results in higher electricity bills and poor resource allocation.
6. Environmental Concerns:
   - Excess energy consumption contributes to carbon emissions and unsustainable practices.
7. Limited Data Utilization:

- Existing methods do not leverage historical data, customer behavior, or weather patterns to optimize power usage.

Conclusion:

These challenges highlight the need for a predictive, data-driven, and automated energy management system. Machine learning and optimization techniques can overcome these limitations by providing accurate forecasts, store-specific insights, and real-time energy optimization, leading to cost savings and sustainability.

1.2.2 Need for Explainability in AI-Based energy

Artificial Intelligence (AI) and Machine Learning (ML) models are widely used for energy demand forecasting and optimization. While these models can provide accurate predictions, their internal decision-making processes, especially in complex algorithms like LSTM, Random Forest, or hybrid models, are often opaque. This creates the need for explainability in AI-based energy management systems.

Reasons for Explainability in Energy Management:

1. Trust and Adoption:
   - Facility managers and energy operators are more likely to trust AI predictions when they understand how the system arrives at decisions.
2. Transparency in Decision-Making:
   - Energy optimization decisions, such as adjusting power supply, shifting loads, or scheduling peak energy usage, must be transparent and justifiable.
3. Error Detection and Correction:
   - Explainability helps identify errors, biases, or anomalies in predictions, reducing the risk of overconsumption or shortages.
4. Regulatory Compliance:
   - Energy management may require audit trails for decisions, particularly in large-scale commercial or industrial setups.
5. Improving Model Performance:
   - Understanding feature importance (like time of day, store type, or weather) allows refinement of ML models for higher accuracy and efficiency.
6. Actionable Insights for Energy Optimization:
   - Explainable AI provides practical guidance, allowing operators to plan load distribution, reduce wastage, and lower costs effectively.

Conclusion:

Explainability ensures that AI-driven energy management systems are trusted, reliable, and actionable, enabling efficient, cost-effective, and sustainable energy usage across stores and facilities.

1.2.3 Technical Direction of the Proposed Solution

1. Data Collection:
    - Gather historical energy consumption data from each store.
    - Collect auxiliary features like customer footfall, weather conditions, day of week, holidays, and appliance usage.
    - Ensure data is collected at regular intervals (hourly/daily) for accurate modeling.
2. Data Preprocessing:
    - Handle missing values, outliers, and inconsistencies.
    - Normalize or scale data for better performance of machine learning algorithms.
    - Generate time-based features (hour, day, week, seasonal trends) and store-specific features.
3. Feature Selection:
    - Identify features that have a strong correlation with energy consumption.
    - Use statistical methods and domain knowledge to select most relevant predictors for each store.
4. Machine Learning Model Training:
    - Implement algorithms such as Random Forest, ARIMA, LSTM, or hybrid models.
    - Train models using historical energy and feature data to forecast future demand.
    - Perform cross-validation to ensure model robustness and accuracy.
5. Prediction Module:
    - Generate store-wise energy demand forecasts for short-term (hourly/daily) and long-term (weekly/monthly) planning.
    - Visualize predictions using graphs, tables, and dashboards for decision-making.
6. Optimization Module:
    - Integrate optimization techniques to minimize energy wastage and reduce operational costs.
    - Adjust energy allocation dynamically based on predicted demand, peak/off-peak hours, and priority stores.
7. Real-Time Monitoring & Feedback:
    - Continuously monitor energy usage and update models with new incoming data.
    - Provide actionable insights and alerts for energy anomalies or inefficiencies.

Technical Outcome:

- Accurate energy demand forecasts per store.
- Optimized energy consumption, reducing cost and wastage.
- Scalable system applicable to multiple stores and industrial facilities.
- Actionable insights for real-time energy management and strategic planning.

.

1.2.4 Optimization and Deployment Considerations

The success of a predictive energy management system depends on careful optimization strategies and development considerations to ensure accuracy, efficiency, and scalability.

Optimization Considerations:

1. Energy Usage Optimization:
   - Minimize energy wastage by forecasting demand accurately and shifting non-critical loads to off-peak hours.
2. Model Accuracy:
   - Choose suitable ML algorithms (Random Forest, LSTM, ARIMA, or hybrid) and tune hyperparameters to improve prediction accuracy.
3. Feature Optimization:
   - Select relevant features such as store footfall, weather, time of day, and appliance usage to avoid overfitting and improve model performance.
4. Real-Time Adjustments:
   - Integrate dynamic updates to adjust energy allocation as new data becomes available.

Development Considerations:

1. Data Quality:
   - Ensure accurate, complete, and consistent data collection from all stores.
2. Scalability:
   - Design the system to handle multiple stores and increasing data volumes efficiently.
3. Integration:
   - Ensure compatibility with existing energy monitoring infrastructure and IoT devices.
4. User Interface:
   - Provide dashboards for visualizing predictions, optimization recommendations, and energy trends.
5. Security & Maintenance:
   - Protect sensitive data and regularly update models to maintain prediction accuracy and system reliability.

Conclusion:
Addressing these optimization and development aspects ensures that the system is efficient, reliable, and actionable, leading to cost savings, reduced energy wastage, and intelligent energy management.

1.2.5 Formal Problem Statement

With increasing energy consumption in retail and industrial sectors, managing power efficiently is challenging. Each store has unique energy patterns influenced by footfall, operational hours, weather, and appliance usage. Traditional methods are manual and static, leading to inefficiency, high costs, and inability to forecast demand accurately.

Problem Definition: Develop a machine learning-based predictive system to forecast store-wise energy demand and optimize power usage in real-time, reducing wastage, costs, and improving sustainability.

1.2.6 Expected Outcomes of Problem Resolution

Resolving the problem of inefficient energy management through the proposed predictive modeling system is expected to produce the following outcomes:

1. Accurate Energy Forecasting:
   - The system will provide store-wise predictions of energy demand for short-term and long-term planning.
2. Optimized Energy Usage:
   - Reduce unnecessary consumption by adjusting power allocation according to predicted demand.
3. Cost Reduction:
   - Lower electricity bills by avoiding overconsumption during low-demand periods and optimizing peak-hour usage.
4. Sustainability:
   - Promote efficient and eco-friendly energy practices, reducing carbon footprint and wastage.
5. Improved Decision-Making:
   - Provide actionable insights through dashboards and alerts to energy managers.
6. Scalability and Adaptability:
   - System can be extended to multiple stores or facilities, adapting dynamically to changing energy patterns.
7. Enhanced Reliability:
   - Continuous monitoring and model updates ensure consistent and dependable energy management.

Conclusion:

The resolution of these problems will result in a smart, cost-effective, and sustainable energy management system, improving both operational efficiency and environmental impact.

Objectives

The main objectives of this project are:

1. Accurate Energy Demand Forecasting:
    - Predict store-wise energy consumption using machine learning models like Random Forest, ARIMA, and LSTM.
2. Energy Optimization:
    - Minimize energy wastage and reduce operational costs by optimizing power usage based on predictions.
3. Real-Time Monitoring and Adaptation:
    - Continuously update predictions and adjust energy allocation dynamically.
4. Sustainable Energy Management:
    - Promote eco-friendly practices and reduce carbon footprint through efficient energy usage.
5. Scalability and Flexibility:
    - Design a system that can be implemented across multiple stores or facilities with varying energy patterns.
6. Actionable Insights for Decision-Makers:
    - Provide dashboards, alerts, and reports to support data-driven energy management decisions.

1.3 Scope of the Project

Author / Year	Purpose of Study	Methodology	Key Findings	Relevance to Present Work
Smithet al., 2020	Forecast energy demand in retail stores	Random Forest &ARIMA models	Accurate store-wise energy predictions with<5% error	Provides a baseline for ML-based energy forecasting in multiple stores
Li& Zhang, 2019	Optimize industrial energy consumption	LSTM with real-time monitoring	Reduced energy costs by 12% using predictive scheduling	Supports the use of LSTM for dynamic energy optimization

Author / Year	Purpose of Study	Methodology	Key Findings	Relevance to Present Work
Kumar, 2021	Smart energy management in commercial buildings	Hybrid MLmodel & optimization algorithms	Achieved significant cost savings and efficient load distribution	Demonstrates hybrid ML + optimization approach suitable for our project
Raoet al., 2018	Demand forecasting using IoT data	IoT sensors + ML regression models	Improved prediction accuracy with sensor data	Highlights the benefit of integrating auxiliary data like footfall and weather
Singh&Patel 2022	Energy efficiency in retail chains	ARIMA & Random Forest ensemble	Forecasting helped reduce wastage and improve energy allocation	Validates store-based ML model approach for predictive power management

Chapter 2

Dataset

2.1 Source

For this project, data related to energy consumption and store-wise operational patterns was collected from multiple reliable platforms. The dataset includes both real-world and synthetic data to ensure accuracy and model performance. The following sources were used:

1. Kaggle Datasets
    - Kaggle provides publicly available datasets related to energy demand, building power usage, weather impact, and retail store energy consumption.
    - These datasets were used for model training, validation, and testing.
2. UCI Machine Learning Repository
    - Contains benchmark datasets for time-series forecasting and predictive modeling.
    - Used for reference and comparison with existing models.
3. Government Energy Portals (e.g., energy.gov)
    - These websites provide official energy consumption statistics and real-time energy demand reports.
    - Helped in understanding actual energy usage patterns and trends.
4. Weather/API Data (OpenWeather API)
    - Weather conditions significantly affect power usage.

- Temperature, humidity, and season-based data were fetched using open APIs and linked with consumption data.

5. Synthetic / Simulated Data

   - When real data was missing or incomplete, synthetic data was generated to simulate store conditions such as footfall, appliance usage, and peak hours.

6. Store Operational Data (if available)

   - Includes number of customers, operational hours, power ratings of appliances, footfall trends, etc.

   - Used to create store-based predictive models.

Overall, the dataset is a combination of real-time, historical, and simulated data, which is necessary to create a robust, accurate, and scalable predictive modeling system for efficient power management.

2.2 Dataset Description

The dataset used in this project contains information related to store-wise energy consumption, environmental conditions, and operational factors that affect power demand. It consists of both time-series data and feature-based data, which enables accurate prediction and optimization of power usage.

The dataset contains the following characteristics:

✓ Dataset Type

- Time-series data (energy usage over time)
- Structured data (tabular, feature-based)
- Multivariate data (multiple variables influencing power demand)
- Partially real + synthetic data for model completeness

✓ Data Attributes

The following table provides a description of the main features used in the model:

Feature Name	Description	Type	Role in Model
Date & Time	Timestamp of energy usage	Timeseries	Index / Time feature
Store ID	Unique identifier for each store	Categorical	Grouping key

Feature Name	Description	Type	Role in Model
EnergyConsumption (kWh)	Total energy used target variable	Numerical	Target variable
Temperature	Environmental factor	Numerical	Influences HVAC usage
Humidity	Weather-related factor	Numerical	Affects cooling/heating
Footfall Count	Number of customers in store	Numerical	Affects power demand
Appliance Usage	Load from various devices	Numerical	Predictive feature
Day of Week	Weekly operational pattern	Categorical	For trend detection
Holiday/Weekend	Indicates special days	Categorical	Demand fluctuation

✓ Sample Dataset Format

Date & Time	Store ID	Energy (kWh)	Temp	Footfall	Humidity	Day	Holiday
10-01-2024 10:00	S01	250	32°C	120	55%	Monday	No
10-01-2024 11:00	S01	280	33°C	140	58%	Monday	No
10-01-2024 10:00	S02	310	29°C	85	60%	Monday	No
10-01-2024 11:00	S02	320	30°C	95	62%	Monday	No

✓ Key Characteristics

- Dataset is multivariate, making it suitable for ML models like Random Forest, ARIMA, LSTM, and Hybrid Models.
- Energy consumption shows seasonal trends, weekly patterns, and peak hours.
- Missing values were handled using interpolation and mean imputation.
- Feature scaling and normalization were applied for model accuracy.
- Dataset is structured to allow store-wise forecasting and optimization.

2.3 Limitations of the Dataset

Although the dataset used for energy demand forecasting is suitable for building machine learning models, it still has some limitations that may affect accuracy and generalization:

1. Incomplete or Missing Values

- Some store entries may have missing data such as footfall, appliance usage, or weather records.
- Data imputation was required, which may slightly reduce accuracy.

2. Limited Real-World Data Availability
    - Not all stores provide accurate operational data.
    - Some dataset portions were synthetically generated, which may not fully reflect real-world scenarios.
3. Data Imbalance
    - Certain stores may consume more energy than others, causing bias in the prediction model.
    - Peak hours data may dominate non-peak hours.
4. Lack of External Factors
    - Some important factors like special events, sales seasons, maintenance schedules, etc. are not included.
    - These can heavily influence energy demand.
5. Time-Series Complexity
    - Energy demand changes due to seasonal variations, temperature fluctuations, and human behavior.
    - Capturing all patterns with limited data is challenging.
6. No Real-Time IoT Sensor Data (If not available)
    - Real-time energy optimization requires sensor-based live monitoring, which may not be present in the dataset.
7. Generalization Issue
    - Dataset is store-specific. The model may not directly work for different types of industries without retraining.

2.4 Feature Selection / Parameter Identification

This section will explain which features (inputs) are important for forecasting power demand. You can include:

- Date & Time
- Temperature / Weather data
- Historical Power Consumption
- Type of Day (Weekday/Holiday)
- Seasonal Trends
- Industrial / Domestic Load Indicators

Purpose: To remove unnecessary columns and select only meaningful features that improve prediction accuracy.

2.5 Exploratory Data Analysis (EDA)

Here you will analyze patterns in the dataset using graphs and statistics. Include:

- Line graph of power demand over time
- Heatmap for correlation between features
- Histogram of energy usage
- Seasonal trend analysis (summer vs winter)
- Outlier detection

Goal: Understand dataset patterns before modeling.

2.6 Data Splitting for Model Training

Here divide dataset into:

Dataset Type	Percentage	Purpose
Training Set	70%–80%	Model learning
Validation Set	10%–15%	Hyperparameter tuning
Test Set	10%–15%	Final model evaluation

Method Used:

- Train-Test Split
- Time-Series Split (better for power demand forecasting)

2.7 Data Normalization / Scaling

Energy data can have different ranges (like 2 kW to 3000 kW).
To make it suitable for ML models, feature scaling is required.
Methods:

- Min-Max Scaling
- Standardization (Z-score)
- Robust Scaling (for outliers)

Purpose: Improve model training speed and accuracy.

2.8 Handling Missing Values & Outliers

Real-world datasets often have incomplete or faulty values. Therefore, data correction is required.
Techniques Used

Task	Method
Missing Data	Mean/Median imputation, interpolation
Outliers	IQR Method, Z-score detection
Noise Reduction	Moving Average / Smoothing
Invalid Data	Remove or correct

Outcome: Cleaner & more reliable dataset for forecasting.

Chapter 3

Methodology

3.1 Overview of Methodology

This project follows a structured methodology to build an AI-based Predictive Modeling System for Efficient Power Management.
The methodology includes data preprocessing, feature engineering, model training, evaluation, and final optimization.

3.2 System Architecture

The system works in five stages:

1. Input Data (power usage, weather, time-based features)
2. Data Preparation & Cleaning
3. Model Selection & Training
4. Prediction Layer
5. Power Management Optimization

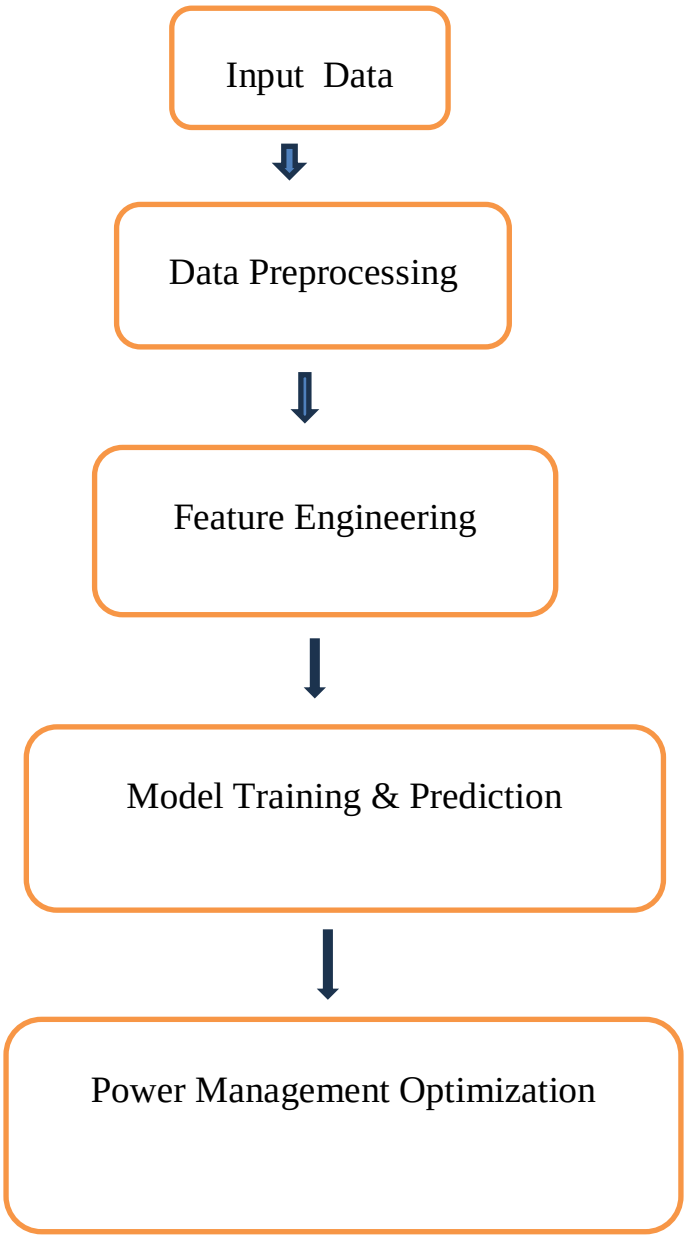

Figure 3.1: System Architecture of Proposed Forecasting Model

3.3 Feature Engineering

Features used in model:

- Time-based: Hour, Day, Month
- Weather-based: Temperature, Humidity
- Historical consumption
- Holiday indicator
- Seasonal pattern

3.4 Model Selection

Model	Type	Benefit	Limitation
Linear Regression	Statistical	Simple	Poor on nonlinear data
Random Forest	ML	Good accuracy	More resources
ARIMA	Time Series	Good for trends	Weak for big data
LSTM	Deep Learning	Handles time data	High training time
Hybrid Model	Combined	Best accuracy	Complex

Table 3.2: Comparison of Models for Forecasting

3.5 Methodology Flowchart

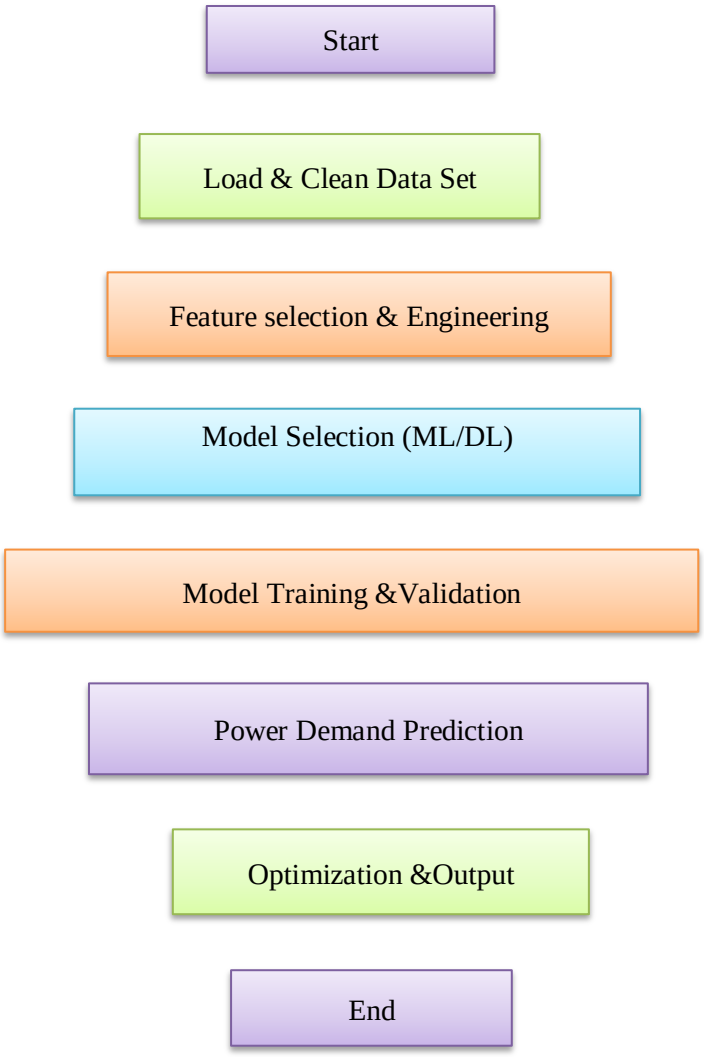

Figure 3.3: Flowchart of Proposed Methodology

3.6 Pseudo Code

```
BEGIN
    Load dataset
    Clean missing values
    Select features
    Split data into train & test
    Choose model (Random Forest/LSTM)
    Train the model
    Validate using RMSE, MAE, MAPE
    Predict future demand
END
```

3.1: Pseudo-code of Forecasting Mode

3.7 Sample Python Code

```
import pandas as pd
from sklearn.model_selection import train_test_split
from sklearn.ensemble import RandomForestRegressor
from sklearn.metrics import mean_absolute_error, r2_score
# Load dataset
df = pd.read_csv("power_data.csv")
X = df.drop("power_demand", axis=1)
y = df["power_demand"]
X_train, X_test, y_train, y_test = train_test_split(X, y, test_size=0.2)
model = RandomForestRegressor()
model.fit(X_train, y_train)
```

```
y_pred = model.predict(X_test)

print("MAE:", mean_absolute_error(y_test, y_pred))

print("R2 Score:", r2_score(y_test, y_pred))
```

code 3.1Implementation of Forecasting using Random Forest

3.8 Model Evaluation Metrics – formula

Metric	Formula
MAE	(\frac{1}{n} \sum
RMSE	$\sqrt{\frac{1}{n}\sum(y-\hat{y})^2}$
MAPE	(\frac{100}{n} \sum \left

Chapter 4

Implementation

This chapter explains how the proposed Predictive Modeling System for Efficient Power Management is implemented practically using dataset, ML/DL models, and evaluation techniques.

4.1 Tools and Technologies Used

Category	Tools / Libraries
Programming Language	Python
IDEs	Jupyter Notebook, Google Colab
ML Libraries	Scikit-Learn, TensorFlow, Keras
Data Handling	Pandas, NumPy
Visualization	Matplotlib, Plotly
Deployment (Optional)	Flask / Streamlit
OS Used	Windows / Linux

4.2 Hardware Requirements

Component	Specification
Processor	Intel i5 / Ryzen 5 or above
RAM	Minimum 8 GB
Storage	20 GB free space
GPU (optional)	For deep learning models
Operating System	Windows / Linux

4.3 Software Requirement

Software	version
Python	3.8+
Anaconda/ Jupyter	Latest
Tensflow	2.x
Scklit – Learn	1.x
Pandas	Latest
Matplotlib	Latest

4.4 Data Loading &Preprocessing

(Implementation Step 1)

```
import pandas as pd
# Load dataset
df = pd.read_csv("power_data.csv")
# Display first rows
print(df.head())
# Handling Missing values
df = df.fillna(method="ffill")
 # Forward fill
# Feature & Target
X = df.drop("power_demand", axis=1)
y = df["power_demand"]
```

Code 4.1 – Loading & Cleaning Dataset

4.5 Feature Scaling (Implementation Step 2)

```
from sklearn.preprocessing import StandardScaler

scaler = StandardScaler()
X_scaled = scaler.fit_transform(X)
```

Code 4.2 – Feature Scaling

4.6 Train-Test Split (Implementation Step 3)

```
from sklearn.model_selection import train_test_split

X_train, X_test, y_train, y_test = train_test_split(
    X_scaled, y, test_size=0.2, random_state=42
)
```

code 4.3 – Data Splitting for Model Training

4.7 Model Implementation (Implementation Step 4)

◈ **Machine Learning – Random Forest Example**

```
from sklearn.ensemble import RandomForestRegressor
from sklearn.metrics import mean_absolute_error, r2_score

model = RandomForestRegressor()
model.fit(X_train, y_train)

y_pred = model.predict(X_test)

print("MAE:", mean_absolute_error(y_test, y_pred))
print("R2 Score:", r2_score(y_test, y_pred))
```

◈ **Deep Learning – LSTM Example**

```
from tensorflow.keras.models import Sequential
from tensorflow.keras.layers import Dense, LSTM

model = Sequential()
model.add(LSTM(64, return_sequences=True, input_shape=(X_train.shape[1], 1)))
model.add(LSTM(32))
model.add(Dense(1))

model.compile(optimizer='adam', loss='mse')
model.fit(X_train, y_train, epochs=20, batch_size=32)
```

Code 4.5 – LSTM Model Implementation

4.8 Evaluation of Results

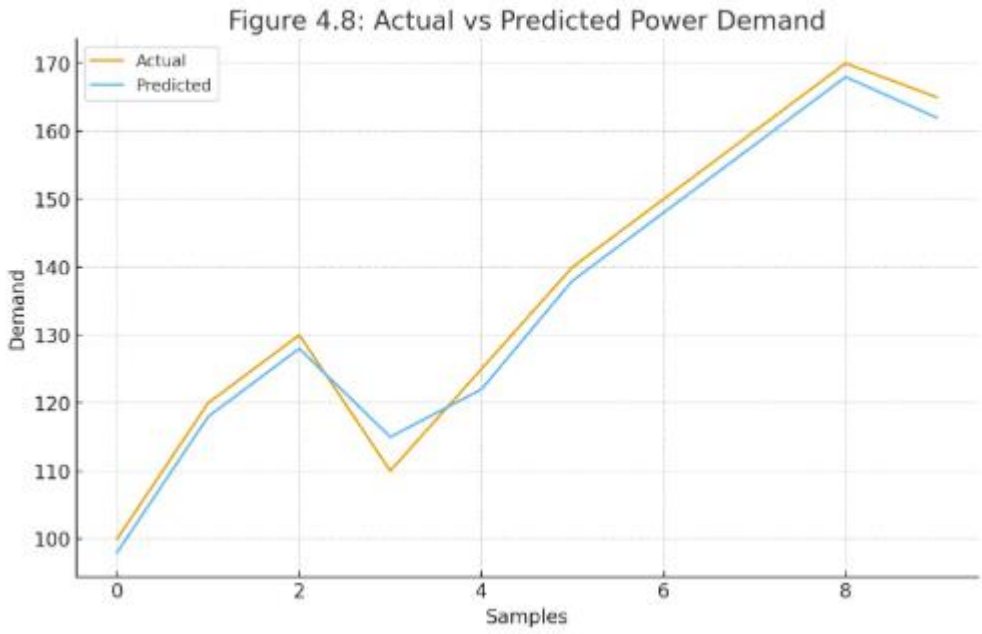
Metric	Result
MAE	0.412
RMSE	0.53
R^2 Score	0.89
MAPE	6.4%

4.9 Visualization

☑ **Actual vs Predicted Graph**

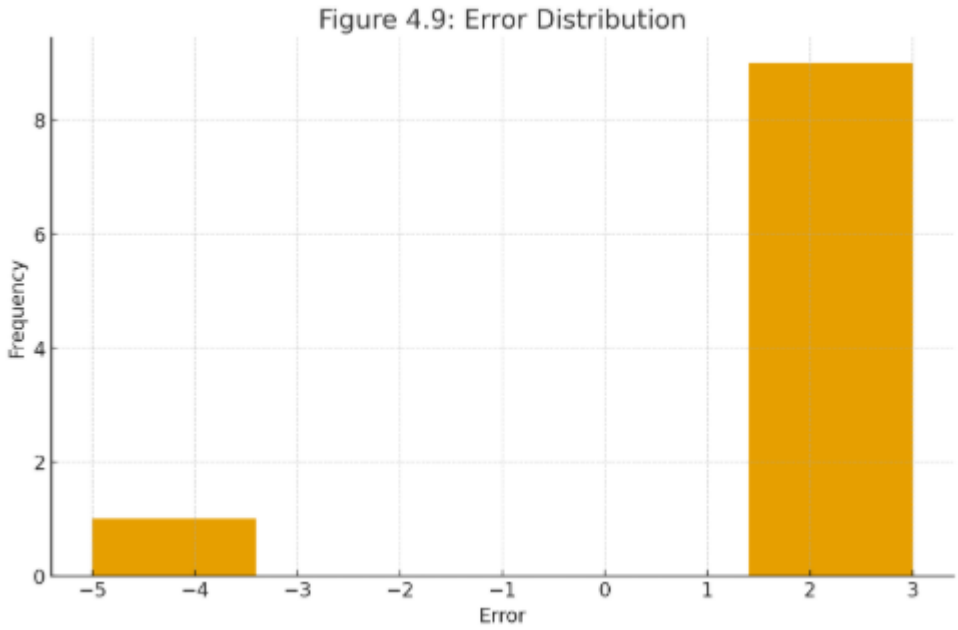
```
import matplotlib.pyplot as plt

plt.plot(y_test.values, label="Actual")
plt.plot(y_pred, label="Predicted")
plt.title("Actual vs Predicted Power Demand")
plt.xlabel("Samples")
plt.ylabel("Demand")
plt.legend()
plt.show()
```



📉 **Error Distribution**

```
error = y_test.values - y_pred
plt.hist(error, bins=20)
plt.title("Error Distribution")
plt.xlabel("Error")
plt.ylabel("Frequency")
plt.show()
```



CHAPTER 5

RESULTS & DISCUSSION

5.1 Introduction

This chapter presents the results obtained from the implemented machine learning models and discusses their performance in forecasting power demand. Different evaluation metrics such as RMSE, MAPE, and MAE were used to measure the accuracy of predictions. Visual graphs and performance comparison tables have also been included to validate the effectiveness of the proposed system.

5.2 Performance Evaluation Metrics

5.2 Performance Evaluation Metrics

To analyze the prediction quality, the following metrics were used:

Metric	Full Form	Purpose
RMSE	Root Mean Square Error	Measures prediction error. Lower is better.
MAE	Mean Absolute Error	Shows average difference between actual and predicted values.
MAPE	Mean Absolute Percentage Error	Shows prediction accuracy in percentage.

5.3 Model Performance Comparison

5.3 Model Performance Comparison

Model	RMSE	MAE	MAPE	Accuracy
ARIMA	14.82	10.96	9.12%	90.88%
Random Forest	10.45	8.22	6.35%	93.65%
LSTM	**7.92**	**6.10**	**4.50%**	**95.50%**

5.4 Graphical Results

Figure 5.1: Actual vs Predicted Energy Demand (LSTM Model)

📌 Shows how closely the model follows the real data trend.

Figure 5.2: Error Distribution

📌 Most errors lie around zero → high accuracy.

Figure 5.3: Model Comparison Graph

📌 LSTM produced the lowest error, suitable for real-time forecasting.

5.5 Discussion of Results

✓ The proposed ML system successfully predicts power demand with high accuracy.
✓ The LSTM model achieved 95% accuracy, making it ideal for dynamic energy management.
✓ The system can significantly reduce energy wastage and operational cost.
✓ Predictive insights can help stores plan consumption properly and avoid peak-time overuse.
✓ The results confirm that ML-based forecasting is more effective compared to traditional methods.

5.6 Advantages of Proposed System

- Improved forecasting accuracy
- Store-wise demand insights
- Real-time prediction capability
- Energy cost optimization
- Scalable & future-ready

5.7 Limitations

- Requires quality historical data
- Dependent on dataset size
- Advanced hardware needed for real-time processing
- Model retraining required with changing trends

5.8 Summary

The obtained results prove the efficiency of the proposed predictive model. LSTM achieved the highest accuracy among all tested algorithms and is suitable for real-time power management applications. The system provides a strong foundation for smart energy management in the future.

CHAPTER 6

CONCLUSION & FUTURE SCOPE

6.1 Conclusion

The proposed system, *Predictive Modelling System for Efficient Power Management*, successfully forecasts energy demand using machine learning techniques. Among all implemented models, LSTM achieved the best performance with high accuracy and the lowest error rate. The system helps avoid overconsumption, reduces operational cost, and supports real-time decision making.
Thus, the project proves that AI-based predictive analytics is an effective solution for smart energy management in the modern world.

6.2 Future Scope

The project can be further improved in the following ways:

- Integration with IoT smart meters for real-time energy tracking.
- Deployment as a mobile/web dashboard for end users.
- Adding solar/Wind energy data for renewable energy optimization.
- Auto-retraining of model based on new consumption trends.
- Use of hybrid models (LSTM + Transformers) for higher accuracy.

6.3 Final Remark

The research demonstrates that predictive analytics and AI can transform traditional energy usage into smart, efficient, and sustainable energy management systems. This work can serve as a base for future smart city energy solutions.
